1 1 INTRODUCTION

2 Ce document présente l'étude quinquennale des taux d'amortissement des principales
3 catégories d'immobilisations corporelles de Gaz Métro en fonction des soldes aux livres au
4 30 septembre 2009.

5 L'application de la présente étude aurait normalement dû prendre effet dans le dossier tarifaire
6 2011. Cependant, l'entrée en vigueur des normes IFRS devait être effective dans le dossier
7 tarifaire 2012. Gaz Métro avait alors demandé à la Régie, le 10 février 2010, le report de
8 l'application de l'étude des taux d'amortissement au dossier tarifaire 2012 en vue de les intégrer
9 aux demandes de modifications de conventions comptables soumises pour l'application des
10 IFRS. La Régie a accepté le report de l'étude dans la décision D-2010-30, rendue le 23 mars
11 2010.

12 Cependant, il est important de mentionner qu'en octobre 2010, le CNC a amendé ces
13 exigences afin de permettre le report de la date d'application des normes IFRS pour les entités
14 admissibles ayant des activités à tarifs réglementés. Cet amendement permet à ces entités de
15 continuer à appliquer les PCGR du Canada pour une période additionnelle d'un an, sans
16 toutefois les y obliger. Par conséquent, Gaz Métro présentera ses demandes de modifications
17 de conventions comptables en vue de la transition vers les normes IFRS dans le cadre d'un
18 dossier distinct.

19 Tel que mentionné dans sa requête du 10 février 2010, Gaz Métro présente l'étude des taux
20 d'amortissement pour application au 1^{er} octobre 2011.

21 L'étude des taux d'amortissement permet d'assurer une répartition équitable de la dépense
22 d'amortissement entre les générations de clients et favorise la juste récupération des
23 investissements. De plus, cet exercice permet l'ajustement de la dépense d'amortissement de
24 Gaz Métro en fonction de l'évolution de la réalité économique. En effet, la durée de vie
25 résiduelle des actifs et la projection des retraits peuvent évoluer de façon différente de ce qui
26 avait été prévu lors de la dernière étude.

27 Gaz Métro utilise la méthode de l'amortissement linéaire, selon un taux spécifique par catégorie
28 d'actifs. Les taux d'amortissement sont établis en fonction de la durée de vie résiduelle des
29 actifs. Cette méthode prend en considération la valeur historique des investissements, les coûts

1 des retraits passés, la prévision des retraits futurs, la valeur de l'amortissement accumulé et la
2 durée de vie résiduelle de l'actif.

3 La nouvelle étude des taux n'engendre pas d'impact significatif sur la dépense d'amortissement
4 annuelle projetée pour l'année 2012. Cet écart non significatif est composé des deux éléments
5 suivants :

- 6 1. Effet des changements de durée de vie établie par un expert indépendant qui est
7 présenté de façon détaillée à la section 4.1 ainsi que dans l'étude présentée à
8 l'Annexe A (diminution de la dépense d'amortissement de 11,3 M\$); et
- 9 2. Changement de méthodologie par rapport à celle utilisée à l'étude de 2004¹ qui fut
10 effectuée selon la méthode ASL alors que la présente étude a été réalisée selon la
11 méthode ELG (augmentation de la dépense d'amortissement de 11,3 M\$).

12 Il est important de noter qu'en 2012, il n'y aura aucun changement quant à l'inclusion de la
13 provision des coûts d'abandon dans les taux d'amortissement. Des changements seront
14 intégrés dans le cadre du dossier tarifaire 2013, suite à la décision de la Régie dans le dossier
15 distinct traitant des changements pour se conformer aux IFRS.

16 **2 TRAITEMENT ACTUEL**

17 **2.1 Normes canadiennes**

18 Selon le traitement utilisé actuellement par Gaz Métro, le coût des immobilisations corporelles
19 est ventilé entre les différentes catégories qui est amorti selon les durées d'utilisation prévues
20 de ces catégories. Ces dernières sont établies selon une étude de taux pour les actifs de
21 distribution, stockage et de transmission. Pour ce qui est des installations générales, les durées
22 d'amortissement sont déterminées à l'interne. Voici les extraits pertinents du chapitre 3061 du
23 *Manuel de l'ICCA* :

24 « .29 Les immobilisations corporelles sont acquises afin de générer des produits ou de fournir un
25 service pendant leur durée de vie utile. À l'exception des terrains, dont la durée de vie est
26 habituellement illimitée, les immobilisations corporelles ont une durée de vie limitée. Leur durée
27 de vie utile correspond normalement à la plus courte des durées physique, technologique,

¹ Décision D-2005-171

1 commerciale ou juridique. L'amortissement est une charge imputée sur les résultats pour rendre
2 compte du fait que la durée de vie est limitée et pour répartir le coût de l'immobilisation
3 corporelle, après défaillance de sa valeur de récupération ou de sa valeur résiduelle, sur les
4 exercices au cours desquels est consommé son potentiel de service. Dans le cas des
5 ressources, on parle d'épuisement ou de déplétion.

6 .30 Le coût d'une immobilisation corporelle constituée d'importantes composantes distinctes est
7 ventilé entre celles-ci lorsqu'il est raisonnablement possible de le faire et que la durée de vie de
8 chacune des composantes peut faire l'objet d'une estimation. Par exemple, les frais initiaux
9 engagés pour la location peuvent être isolés à titre de composante distincte du coût d'un
10 immeuble destiné à la location, et les moteurs peuvent constituer une composante distincte d'un
11 aéronef. »

12 Les catégories d'immobilisations corporelles sont identifiées en considérant notamment les
13 caractéristiques des actifs, leur nature, leur durée d'utilisation prévue et les activités auxquelles
14 elles se rattachent. Un seul taux d'amortissement est déterminé pour chacune des catégories
15 d'immobilisations corporelles.

16 **2.2 Traitement réglementaire**

17 L'ordonnance GC-1 et GC-24 suggère une charte de comptes de grand livre mais ne fournit pas
18 d'indications quant aux catégories d'actifs à utiliser.

19 La valeur historique, l'amortissement cumulé ainsi que la dépense annuelle d'amortissement
20 (établie à l'aide des taux approuvés par la Régie) sont présentés annuellement par catégorie
21 lors de l'élaboration du dossier tarifaire.

22 **3 DÉMARCHE**

23 **3.1 Analyses – identification de nouvelles catégories**

24 Des ateliers de travail ont été réalisés à l'interne avec les responsables de chaque groupe
25 d'actifs. Ces rencontres avaient pour objectif de revoir les catégories actuelles des
26 immobilisations corporelles et d'établir si des modifications à ces catégories étaient nécessaires
27 pour se conformer aux exigences de la norme IAS 16.

28 Ainsi, des analyses ont été effectuées par catégorie d'actifs afin de voir si celles-ci répondaient
29 à la définition d'une composante. Les responsables se sont interrogés sur les différents

1 éléments contenus dans une catégorie ainsi que sur leur durée d'utilisation prévue afin de voir
2 si ceux-ci ne devraient pas être séparés en composantes distinctes.

3 Le 5 octobre 2009, lors d'une rencontre d'information avec le personnel technique de la Régie
4 et les intervenants portant sur les immobilisations corporelles, des conclusions préliminaires
5 quant aux composantes éventuelles en vertu des normes IFRS ont été présentées. Afin de
6 conclure sur la nécessité d'utiliser ces composantes, Gaz Métro a simulé l'effet de ces
7 composantes sur la dépense annuelle d'amortissement et la valeur comptable nette, basé sur
8 les immobilisations corporelles détenues au 30 septembre 2009. À la lumière de ces analyses, il
9 est ressorti que l'utilisation de composantes supplémentaires avait le même effet que d'utiliser
10 le taux moyen pondéré d'amortissement, tel qu'effectué actuellement. De cette façon,
11 Gaz Métro a conclu que les catégories d'immobilisations corporelles actuelles rencontrent les
12 exigences de l'IAS 16 et qu'ainsi, aucune modification à ce niveau n'est requise.

13 Toutefois, dans le cadre de ces analyses, des possibilités d'amélioration des catégories
14 actuelles ont été identifiées pour certains actifs. Ces modifications sont également valides en
15 vertu des PCGR canadiens et font parties du processus d'amélioration continue de Gaz Métro.

16 **3.2 Taux d'amortissement des actifs de distribution, stockage et de
17 transmission**

18 L'exécution de cette analyse statistique et prévisionnelle a été confiée à Larry Kennedy,
19 consultant spécialisé dans ce domaine, de la firme Gannett Fleming. Son mandat consistait à
20 revoir les taux d'amortissement des catégories d'actifs de distribution, de stockage ainsi que de
21 transmission en tenant compte des informations historiques.

22 Pour chacun des groupes d'actifs, une courbe de mortalité a été établie afin de déterminer une
23 durée de vie moyenne par catégorie d'actifs. Pour ce faire, Gaz Métro a fourni à M. Kennedy les
24 soldes au 30 septembre 2009 de la valeur historique, de l'amortissement accumulé, des
25 additions et des retraits de toutes les catégories d'actifs ventilées selon l'année de mise en
26 service. À partir de ces informations, la durée de vie², la durée de vie résiduelle³ ainsi que
27 l'évaluation des coûts de retraits de chaque actif ont été déterminées.

² La durée de vie équivaut à l'espérance de vie d'un groupe d'actifs au moment de son acquisition.

³ La durée de vie résiduelle représente la durée de vie restante de l'ensemble d'un groupe d'actifs. Cette durée tient compte de l'âge moyen du groupe d'actifs par rapport à sa durée de vie établie au départ.

1 Des simulations ont été effectuées pour permettre la sélection de la courbe de mortalité de la
2 catégorie d'actifs qui correspond le mieux aux données réelles de chaque groupe d'actifs
3 étudié. Ces courbes statistiques proviennent de l'Iowa State University.

4 M. Kennedy a rencontré les ingénieurs responsables de la conception et de la gestion des actifs
5 de distribution, de stockage et de transmission de Gaz Métro. Ces rencontres avaient pour but
6 de connaître leur opinion sur la durée de vie des actifs du réseau de Gaz Métro. De même, il
7 voulait connaître les projets d'investissements à venir qui pourraient influencer de façon
8 significative l'évaluation du niveau futur de la valeur historique, dû aux acquisitions ou
9 dispositions anticipées d'immobilisations corporelles.

10 **3.2.1 Méthodes de détermination des taux d'amortissement**

11 Deux méthodes peuvent être employées pour la détermination des taux d'amortissement.
12 Avec la méthode ASL, la durée de vie moyenne résiduelle est calculée par catégorie à partir
13 de la durée résiduelle entre la date d'acquisition et la durée moyenne de vie retenue pour
14 cette catégorie. Ainsi, les actifs ayant une durée de vie plus longue que la moyenne dans la
15 catégorie permettent de récupérer la déficience générée (déviation d'amortissement
16 résultant des pertes sur disposition) par les actifs ayant une durée de vie plus courte que la
17 moyenne.

18 La méthode ELG prend, quant à elle, en compte le fait que dans une catégorie d'actifs, pour
19 une année donnée, certains actifs sont retirés avant l'atteinte de la durée de vie projetée et
20 ce, pour diverses raisons. La durée de vie de la catégorie est donc établie à l'aide de la
21 somme des durées de vie moyennes qui tient compte de l'historique des retraits par année
22 d'acquisition. Il en résulte un niveau plus élevé de dépense d'amortissement plus tôt dans la
23 vie d'un groupe d'actif.

24 L'utilisation de la méthode EGL est plus précise que la méthode ASL puisqu'elle tient
25 compte du fait que certains actifs sont retirés avant la fin de leur durée de vie utile. Ainsi, la
26 dépense d'amortissement est plus représentative du coût d'utilisation des actifs.

27 Les études précédentes furent réalisées selon la méthode ASL. Cependant, M. Kennedy
28 recommande l'utilisation de la méthode ELG qui conduit à établir une charge
29 d'amortissement qui reflète mieux la durée d'utilisation des actifs.

1 **3.3 Taux d'amortissement des actifs des installations générales**

2 Pour ce qui est des catégories relatives aux installations générales, les taux d'amortissement
3 ont été analysés à l'interne, tel qu'effectué dans les années précédentes. Compte tenu de la
4 nature des immobilisations incluses dans les catégories des installations générales, l'estimation
5 de la durée de vie de ces actifs est plus facilement déterminable et conséquemment,
6 l'implication d'un expert en étude de taux n'est pas nécessaire. Des ateliers de travail ont été
7 réalisés avec les responsables à l'interne des actifs étudiés. Ces rencontres avaient pour
8 objectif, compte tenu de l'approche par composantes dans le cadre du projet de conversion
9 vers les normes IFRS, de revoir les catégories, de définir les changements et d'évaluer les taux
10 d'amortissement appropriés. La durée de vie des actifs, la durée d'amortissement, les retraits
11 prévus et le rythme des investissements futurs ont aussi été validés au cours de ces rencontres.

12 Peu de changements ayant des impacts significatifs ont été effectués sur ces catégories
13 puisque des modifications importantes avaient déjà été apportées à celles-ci lors de
14 l'élaboration du dossier tarifaire 2009. En effet, à la demande de la Régie, dans la décision
15 D-2008-067 émise le 8 mai 2008 dans le cadre du Rapport annuel au 30 septembre 2007, des
16 modifications aux taux d'amortissement et aux catégories des installations générales avaient
17 été effectuées.

18 **4 RÉSULTAT**

19 Les résultats de l'étude des taux d'amortissement se divisent en deux parties. D'une part, les
20 actifs étudiés par Gannett Fleming sont constitués des actifs de distribution, de stockage et de
21 transmission. Les résultats de l'étude de la firme Gannett Fleming sont présentés à l'annexe A.

22 D'autre part, les résultats de l'étude des installations générales réalisée par Gaz Métro sont
23 intégrés à l'annexe B.

24 Il faut noter que pour certains actifs, il ne fut pas nécessaire de procéder à une étude. C'est le
25 cas, entre autres, des actifs non amortissables tels que les terrains, les droits de mutation et les
26 travaux en cours. Également, certains actifs, tels que les contributions et les subventions, ont
27 les mêmes taux d'amortissement que les actifs auxquels ils sont reliés, soit les branchements
28 d'immeubles. Par conséquent, les taux d'amortissement de ces actifs seront ajustés en fonction
29 des nouveaux taux de ces catégories.

1 Globalement, la dépense d'amortissement de l'année 2012, toutes catégories d'immobilisations
2 confondues, aurait été de 87,7 M\$ comparativement à une prévision de 87,6 M\$ en fonction des
3 taux actuels. L'annexe B présente l'analyse détaillée des impacts sur la dépense
4 d'amortissement par catégorie d'immobilisations.

5 Afin d'être en mesure de comparer les informations présentées dans l'étude précédente avec
6 les informations incluses dans la présente étude, le tableau suivant résume l'impact sur la
7 dépense d'amortissement de chacune des étapes réalisées dans le cadre de l'étude des taux
8 d'amortissement.

Description de l'écart	Augmentation (diminution) de la dépense (en milliers de \$)
Modification des taux d'amortissement - selon méthode ASL	(11 298)
Changement de méthode d'amortissement - ASL vs ELG	11 335
TOTAL	37

9

10 Dans un premier temps, l'impact lié à la modification des durées de vie des actifs, et par
11 conséquent des taux d'amortissement, a été isolé. Pour ce faire, la dépense d'amortissement
12 de la Cause tarifaire 2012, établie en utilisant les taux de l'étude de 2004 et selon la méthode
13 ASL (incluant les coûts d'abandon), a été comparée à la dépense d'amortissement 2012 établie
14 selon les taux de l'étude de 2010 et selon la méthode ASL (incluant les coûts d'abandon). La
15 portion attribuable à cet élément entraîne une baisse de la dépense de 11,3 M\$. Celle-ci
16 s'explique principalement par l'augmentation de la durée de vie moyenne de certaines
17 catégories au niveau des actifs de distribution, de stockage et de transmission, conformément à
18 l'évaluation faite par M. Kennedy.

19 Dans un deuxième temps, l'effet du passage de la méthode ASL à la méthode ELG a été établi
20 en comparant la dépense d'amortissement 2012 selon les taux de l'étude 2010 et la méthode
21 ASL (incluant les coûts d'abandon) à la dépense d'amortissement 2012 selon les taux de
22 l'étude 2010 et la méthode ELG (en incluant aussi les coûts d'abandon). L'impact de cet
23 élément représente une hausse de 11,3 M\$ de la dépense d'amortissement.

1 **4.1 La modification des taux des actifs de distribution, de stockage et de**
 2 **transmission**

3 Une baisse significative des taux d'amortissement des branchements d'immeubles et des
 4 conduites principales est recommandée par le consultant. À la suite de l'analyse basée sur les
 5 retraits passés, les durées de vie proposées pour ces catégories d'immobilisation ont augmenté
 6 de façon significative.

7 Voici un tableau récapitulatif des changements importants :

8 Voici un tableau récapitulatif des changements importants :

Catégorie	Description catégorie	Taux actuel (1)	Estimation durée vie utile actuelle	Taux proposé (2)	Estimation durée de vie utile proposée	Impact dépense amortissement 2011
Z1100	Distribution branchemen acier	3,77 %	33	2,66%	45	(1,6 M\$)
Z1102	Distribution branchemen plastique direct	3,63 %	35	3,19 %	50	(2,4 M\$)
Z1103	Distribution branchemen plastique inséré	3,87 %	37	2,45 %	50	(1,0 M\$)
Z1150	Distribution conduite acier	3,06 %	42	2,82 %	50	(1,5 M\$)
Z1151	Distribution conduite plastique direct	2,21 %	50	1,98 %	60	(1,7 M\$)
Z1152	Distribution conduite plastique inséré	1,97 %	50	1,75%	60	(0,1M\$)
Z3100	Transmission conduite	4,00 %	25	0,46 %	65	(1,5 M\$)
Z1200	Compteurs	4,82 %	22	9,16 %	18	6,0 M\$
Autres catégories	Autres catégories	divers	divers	divers	divers	(3,8 M\$)
Total						(7,6 M\$)

9 (1) : ASL avec coût abandon

10 (2) : ELG avec coût abandon

11 Il est important de mentionner que la révision à la baisse de la durée de vie moyenne des
 12 compteurs prend en compte un nouveau facteur relié aux normes de Mesures Canada. Ce
 13 facteur a entraîné une augmentation du taux d'amortissement de 4,82 % à 9,16 %. En effet, les
 14 changements apportés aux normes de Mesure Canada au niveau de l'inspection auront pour
 15 effet de réduire la durée d'utilité prévue des compteurs puisqu'ils seront retirés plus rapidement.
 16 L'ajustement de la durée de vie permettra d'éviter des pertes futures sur les dispositions de

1 compteurs. Cette modification a un impact estimé à la hausse de 6,0 M\$ sur la dépense
2 d'amortissement.

3 Dans la décision D-2011-048, la Régie demande à Gaz Métro de valider la vie utile des actifs
4 touchés par le projet Senneville dans le cadre de la mise à jour de l'étude d'amortissement.
5 Suite à la modification des taux d'amortissement à la baisse, la durée de vie utile des actifs du
6 projet Senneville sera de 50 ans.

7 **5 PROPOSITION DE GAZ MÉTRO**

8 Tel que mentionné précédemment, les catégories utilisées actuellement par Gaz Métro
9 répondent aux critères de l'IAS 16. Cependant, Gaz Métro demande des changements visant à
10 maintenir une saine gestion de ses immobilisations. Ces changements se composent
11 majoritairement d'ajouts de catégories relativement aux actifs de stockage et aux installations
12 générales.

13 Gaz Métro demande un changement de taux pour les catégories de machinerie lourde et de
14 remorques passant de 10 % (10 ans) à 12,5 % (8 ans) ainsi que l'ajout d'une catégorie pour
15 l'équipement et l'outillage avec un taux de 8,33 % (12 ans). Actuellement, ces équipements sont
16 regroupés dans les deux catégories de machineries et d'équipements et d'outillages et sont
17 amortis respectivement sur 8 ans et 25 ans. Tel que mentionné précédemment, ces
18 améliorations ont été identifiées à la suite de la revue des catégories dans le cadre des
19 analyses sur l'approche par composantes et permettraient une répartition équitable de la
20 dépense d'amortissement entre les générations de clients et favoriserait la juste récupération
21 des investissements.

22 Globalement, les modifications aux catégories des installations générales ont un impact à la
23 hausse inférieur à 0,1 M\$ sur la dépense d'amortissement.

24 **6 MODALITÉ D'APPLICATION**

25 Pour la cause tarifaire 2012, Gaz Métro demande à la Régie d'autoriser :

- 26 a) L'utilisation de la méthode ELG plutôt que la méthode ASL;
- 27 b) la modification des taux d'amortissement applicables à certaines catégories d'actifs tel
28 que plus explicitement à l'annexe B;

1 c) la création des nouvelles catégories d'immobilisation décrites à l'annexe C, ainsi que les
2 taux d'amortissement afférents;

3 d) la modification des taux d'amortissement applicables à certaines catégories
4 d'immobilisations déjà existantes, tel que plus amplement explicité à l'annexe C.

5 **7 IMPACT TARIFAIRES DES MODIFICATIONS DES IMMOBILISATIONS**
6 **CORPORELLES**

7 L'impact des modifications des taux d'amortissements et des catégories d'immobilisations
8 corporielles est une augmentation sur la dépense d'amortissement de 37 163 \$ pour l'année
9 d'application 2012.

10 **8 CONCLUSION**

11 La mise à jour de la présente étude des taux d'amortissement permettrait de refléter une
12 dépense annuelle d'amortissement conforme à la réalité économique actuelle et à l'application
13 des normes comptables en vigueur. Cette étude nous amène à revoir à la hausse la dépense
14 de Gaz Métro de 37 163 \$, ce qui représente une augmentation de 0,02 % par rapport à la
15 dépense d'amortissement actuelle. Il est toutefois important de rappeler que cet impact tient
16 compte de l'inclusion des coûts d'abandon qui sont maintenus dans les taux d'amortissement
17 en 2012. Tel que mentionné précédemment, une preuve portant sur le traitement des coûts
18 d'abandon sera déposée dans le cadre des demandes de modification de convention comptable
19 IFRS.

Mme Caroline Plamondon, CMA
Chef de service, Immobilization et contrôle des coûts
Société en Commandite Gaz Métro
1717, rue du Havre
Montréal QC H2K 2X3

Attention: Mme. Caroline Plamondon,

Ladies and Gentlemen,

Pursuant to your request, we have conducted a depreciation study related to the gas distribution, transmission and stockage plant assets of Gaz Metro. ("or the company") as of September 30, 2009. Our report presents a description of the methods used in the estimation of depreciation, the statistical analyses of service life and the summary and detailed tabulations of annual and accrued depreciation.

The calculated annual depreciation accrual rates presented in the report are applicable to plant in service as of September 30, 2009. The depreciation rates are based on the straight-line remaining life method using the equal life group procedure. A periodic review of the depreciation rates using the same estimates and methods is recommended.

Respectfully submitted,

GANNETT FLEMING, INC.
VALUATION AND RATE DIVISION

PART I. INTRODUCTION

PART I. INTRODUCTION

SCOPE

This report sets forth the results of the depreciation study conducted for the gas distribution, transmission and stockage assets of Gaz Metro. (or “the company”) as of September 30, 2009 to determine the annual depreciation accrual rates and amounts for ratemaking purposes applicable to the original cost of plant as of September 30, 2009.

The depreciation accrual rates presented herein are based on generally-accepted methods and procedures for calculating depreciation. The estimated survivor curves used in this report are based on studies incorporating data through 2009.

Part I, Introduction, contains statements with respect to the scope of the report and the basis of the study. Part II, Methods Used in the Calculation of Depreciation, presents the methods used in the estimation of average service lives, survivor curves, and net salvage percentages and in the calculation of depreciation. Part III, Results of Study, presents a summary of annual depreciation, the statistical analyses of service lives and net salvage estimates, and the detailed tabulations of annual depreciation.

BASIS OF THE STUDY

Depreciation. The depreciation accrual rates and accrued depreciation were calculated using the straight line method, the remaining life basis and the equal life group (ELG) procedure. The calculation was based on the attained ages and estimated service life and net salvage characteristics for each depreciable group of assets.

Service Life Estimates. The method of estimating service life consisted of compiling the service life history of the plant accounts and subaccounts, reducing this

history to trends through the use of analytical techniques that have been generally accepted in various regulatory jurisdictions, and forecasting the trend of survivors for each depreciable group on the basis of interpretations of past trends and consideration of the company plans for the future. The combination of the historical trend and the estimated future trend yielded a complete pattern of life characteristics from which the average service life was derived. The service life estimates used in the depreciation calculation incorporated historical data compiled through September 30, 2009. Such data included plant additions, retirements, transfers and other plant activity.

A general understanding of the function of the plant and information with respect to the reasons for past retirements and the expected future causes of retirement was obtained through contact with the company representatives. The information gained though these discussions with the company representatives was also used in the developments of the average service life estimates.

Net Salvage Estimates. The estimates of net salvage were based on judgment which incorporated analyses of available historical data, a review of policies and outlook with management, a general knowledge of the gas utility industry, and comparison of the net salvage estimates from studies of other gas utilities. The estimates of net salvage are expressed as the average net percent of the investment to be incurred or recovered upon its retirement.

International Financial Reporting Standards. The Canadian Accounting Standards Board (ACSB) announced that Canadian Generally Accepted Accounting Principles (GAAP) will be converged to comply for reporting purposes with the International Financial Reporting Standards (IFRS) by 2011. However, in late 2010 the

ACsB announced that a one-year exemption to the previous mandated January 1, 2011 implementation date would be made available to rate regulated entities within Canada. In preparation for the implementation of IFRS this depreciation study has developed depreciation rates and parameters that, in the view of Gannett Fleming, are in compliance with the new standard.

RECOMMENDATIONS

The calculated annual depreciation accrual rates set forth herein apply specifically to plant in service as of September 30, 2009. Continued surveillance and periodic revisions are normally required to maintain continued use of appropriate depreciation rates.

The depreciation rates should be reviewed periodically to reflect the changes that result from plant account activity. A depreciation reserve deficiency or surplus will develop if future capital expenditures vary significantly from those anticipated in this study.

The survivor curves used in this study should be the basis for periodic recalculations. Complete depreciation studies, which reevaluate these parameters, should be performed every three to five years.

PART II. METHODS USED IN THE
ESTIMATION OF DEPRECIATION

PART II. METHODS USED IN THE CALCULATION OF DEPRECIATION

DEPRECIATION

Depreciation, in public utility regulation, is the loss in service value not restored by current maintenance, incurred in connection with the consumption or prospective retirement of utility plant in the course of service from causes which are known to be in current operation and against which the utility is not protected by insurance. Among causes to be given consideration are wear and tear, deterioration, action of the elements, inadequacy, obsolescence, changes in the art, changes in demand, and the requirements of public authorities.

Depreciation, as used in accounting, is a method of distributing fixed capital costs, less net salvage, over a period of time by allocating annual amounts to expense. Each annual amount of such depreciation expense is part of that year's total cost of providing natural gas distribution service. Normally, the period of time over which the fixed capital cost is allocated to the cost of service is equal to the period of time over which an item renders service, that is, the item's service life. The most prevalent method of allocation is to distribute an equal amount of cost to each year of service life. This method is known as the straight-line method of depreciation.

The calculation of annual and accrued depreciation based on the straight line method requires the estimation of survivor curves and the selection of group depreciation procedures. These subjects are discussed in the sections that follow.

ESTIMATION OF SURVIVOR CURVES

Survivor Curves. The use of an average service life for a property group implies that the various units in the group have different lives. Thus, the average life may be obtained by determining the separate lives of each of the units, or by constructing a survivor curve by plotting the number of units which survive at successive ages. A discussion of the general concept of survivor curves is presented. Also, the Iowa type survivor curves are reviewed.

The survivor curve graphically depicts the amount of property existing at each age throughout the life of an original group. From the survivor curve, the average life of the group, the remaining life expectancy, the probable life, and the frequency curve can be calculated. In Figure 1, a typical smooth survivor curve and the derived curves are illustrated. The average life is obtained by calculating the area under the survivor curve, from age zero to the maximum age, and dividing this area by the ordinate at age zero. The remaining life expectancy at any age can be calculated by obtaining the area under the curve, from the observation age to the maximum age, and dividing this area by the percent surviving at the observation age. For example, in Figure 1, the remaining life at age 30 is equal to the crosshatched area under the survivor curve divided by 29.5 percent surviving at age 30. The probable life at any age is developed by adding the age and remaining life. If the probable life of the property is calculated for each year of age, the probable life curve shown in the chart can be developed. The frequency curve presents the number of units retired in each age interval and is derived by obtaining the differences between the amount of property surviving at the beginning and at the end of each interval.

Iowa Type Curves. The range of survivor characteristics usually experienced by utility and industrial properties is encompassed by a system of generalized survivor curves known as the Iowa type curves. There are four families in the Iowa system, labeled in accordance with the location of the modes of the retirements in relationship to the average life and the relative height of the modes. The left moded curves, presented in Figure 2, are those in which the greatest frequency of retirement occurs to the left of, or prior to, average service life. The symmetrical moded curves, presented in Figure 3, are those in which the greatest frequency of retirement occurs at average service life. The right moded curves, presented in Figure 4, are those in which the greatest frequency occurs to the right of, or after, average service life. The origin moded curves, presented in Figure 5, are those in which the greatest frequency of retirement occurs at the origin, or immediately after age zero. The letter designation of each family of curves (L, S, R or O) represents the location of the mode of the associated frequency curve with respect to the average service life. The numbers represent the relative heights of the modes of the frequency curves within each family.

The Iowa curves were developed at the Iowa State College Engineering Experiment Station through an extensive process of observation and classification of the ages at which industrial property had been retired. A report of the study which resulted in the classification of property survivor characteristics into 18 type curves, which constitute three of the four families, was published in 1935 in the form of the Experiment Station's Bulletin 125.¹ These types of curves have also been presented

subsequent Experiment Station bulletins and in the text, "Engineering Valuation and Depreciation."² In 1957, Frank V. B. Couch, Jr., an Iowa State College graduate student, submitted a thesis³ presenting his development of the fourth family consisting of the four O type survivor curves.

Retirement Rate Method of Analysis. The retirement rate method is an actuarial method of deriving survivor curves using the average rates at which property of each age group is retired. The method relates to property groups for which aged accounting experience is available or for which aged accounting experience is developed by statistically aging unaged amounts and is the method used to develop the original stub survivor curves in this study. The method (also known as the annual rate method) is illustrated through the use of an example in the following text, and is also explained in several publications, including "Statistical Analyses of Industrial Property Retirements,"⁴ "Engineering Valuation and Depreciation,"⁵ and "Depreciation Systems."⁶

The average rate of retirement used in the calculation of the percent surviving for the survivor curve (life table) requires two sets of data: first, the property retired during a period of observation, identified by the property's age at retirement; and second, the property exposed to retirement at the beginnings of the age intervals during the same period. The period of observation is referred to as the experience band, and the band of years which represent the installation dates of the

property exposed to retirement during the experience band is referred to as the placement band. An example of the calculations used in the development of a life table follows. The example includes schedules of annual aged property transactions, a schedule of plant exposed to retirement, a life table and illustrations of smoothing the stub survivor curve.

Schedules of Annual Transactions in Plant Records. The property group used to illustrate the retirement rate method is observed for the experience band 2000-2009 during which there were placements during the years 1995-2009. In order to illustrate the summation of the aged data by age interval, the data were compiled in the manner presented in Tables 1 and 2 on the following pages. In Table 1, the year of installation (year placed) and the year of retirement are shown. The age interval during which a retirement occurred is determined from this information. In the example which follows, \$10,000 of the dollars invested in 1995 was retired in 2000. The \$10,000 retirement occurred during the age interval between 4½ and 5½ years on the basis that approximately one-half of the amount of property was installed prior to and subsequent to July 1 of each year. That is, on the average, property installed during a year is placed in service at the midpoint of the year for the purpose of the analysis. All retirements also are stated as occurring at the midpoint of a one-year age interval of time, except the first age interval which encompasses only one-half year.

The total retirements occurring in each age interval in a band are determined by summing the amounts for each transaction year-installation year combination for that age interval. For example, the total of \$143,000 retired for age interval 4½-5½ is the sum of the retirements entered on Table 1 immediately above the staircase line drawn

^c Sale with Continued Use
Parentheses denote Credit amount.

on the table beginning with the 2000 retirements of 1995 installations and ending with the 2000 retirements of the 2002 installations. Thus, the total amount of 143 for age interval 4½-5½ equals the sum of:

$$10 + 12 + 13 + 11 + 13 + 13 + 15 + 17 + 19 + 20.$$

In Table 2, other transactions which affect the group are recorded in a similar manner. The entries illustrated include transfers and sales. The entries which are credits to the plant account are shown in parentheses. The items recorded on this schedule are not totaled with the retirements, but are used in developing the exposures at the beginning of each age interval.

Schedule of Plant Exposed to Retirement. The development of the amount of plant exposed to retirement at the beginning of each age interval is illustrated in Table 3 on page II-15. The surviving plant at the beginning of each year from 2000 through 2009 is recorded by year in the portion of the table headed "Annual Survivors at the Beginning of the Year." The last amount entered in each column is the amount of new plant added to the group during the year. The amounts entered in Table 3 for each successive year following the beginning balance or addition are obtained by adding or subtracting the net entries shown on Tables 1 and 2. For the purpose of determining the plant exposed to retirement, transfers-in are considered as being exposed to retirement in this group at the beginning of the year in which they occurred, and the sales and transfers-out are considered to be removed from the plant exposed to retirement at the beginning of the following year. Thus, the amounts of plant shown at the beginning of each year are the amounts of plant from each placement year

^a Additions during the year.

considered to be exposed to retirement at the beginning of each successive transaction year. For example, the exposures for the installation year 2004 are calculated in the following manner:

Exposures at age 0	= amount of addition	= \$750,000
Exposures at age ½	= \$750,000 - \$ 8,000	= \$742,000
Exposures at age 1½	= \$742,000 - \$18,000	= \$724,000
Exposures at age 2½	= \$724,000 - \$20,000 - \$19,000	= \$685,000
Exposures at age 3½	= \$685,000 - \$22,000	= \$663,000

For the entire experience band 2000-2009, the total exposures at the beginning of an age interval are obtained by summing diagonally in a manner similar to the summing of the retirements during an age interval (Table 1). For example, the figure of 3,789, shown as the total exposures at the beginning of age interval 4½-5½, is obtained by summing:

$$255 + 268 + 284 + 311 + 334 + 374 + 405 + 448 + 501 + 609.$$

Original Life Table. The original life table, illustrated in Table 4 on page II-18, is developed from the totals shown on the schedules of retirements and exposures, Tables 1 and 3, respectively. The exposures at the beginning of the age interval are obtained from the corresponding age interval of the exposure schedule, and the retirements during the age interval are obtained from the corresponding age interval of the retirement schedule. The retirement ratio is the result of dividing the retirements during the age interval by the exposures at the beginning of the age interval. The percent surviving at the beginning of each age interval is derived from survivor ratios, each of which equals one minus the retirement ratio. The percent surviving is developed by starting with 100% at age zero and successively multiplying the percent surviving at the beginning of each interval by the survivor ratio, i.e., one minus the

retirement ratio for that age interval. The calculations necessary to determine the percent surviving at age 5½ are as follows:

Percent surviving at age 4½	=	88.15
Exposures at age 4½	=	3,789,000
Retirements from age 4½ to 5½	=	143,000
Retirement Ratio	=	$143,000 \div 3,789,000 = 0.0377$
Survivor Ratio	=	$1.000 - 0.0377 = 0.9623$
Percent surviving at age 5½	=	$(88.15) \times (0.9623) = 84.83$

The totals of the exposures and retirements (columns 2 and 3) are shown for the purpose of checking with the respective totals in Tables 1 and 3. The ratio of the total retirements to the total exposures, other than for each age interval, is meaningless.

The original survivor curve is plotted from the original life table (column 6, Table 4). When the curve terminates at a percent surviving greater than zero, it is called a stub survivor curve. Survivor curves developed from retirement rate studies generally are stub curves.

Smoothing the Original Survivor Curve. The smoothing of the original survivor curve eliminates any irregularities and serves as the basis for the preliminary extrapolation to zero percent surviving of the original stub curve. Even if the original survivor curve is complete from 100% to zero percent, it is desirable to eliminate any irregularities, as there is still an extrapolation for the vintages which have not yet lived to the age at which the curve reaches zero percent. In this study, the smoothing of the original curve with established type curves was used to eliminate irregularities in the original curve.

Column 2 from Table 3, Column 12, Plant Exposed to Retirement.

Column 3 from Table 1, Column 12, Retirements for Each Year.

Column 4 = Column 3 divided by Column 2.

Column 5 = 1.0000 minus Column 4.

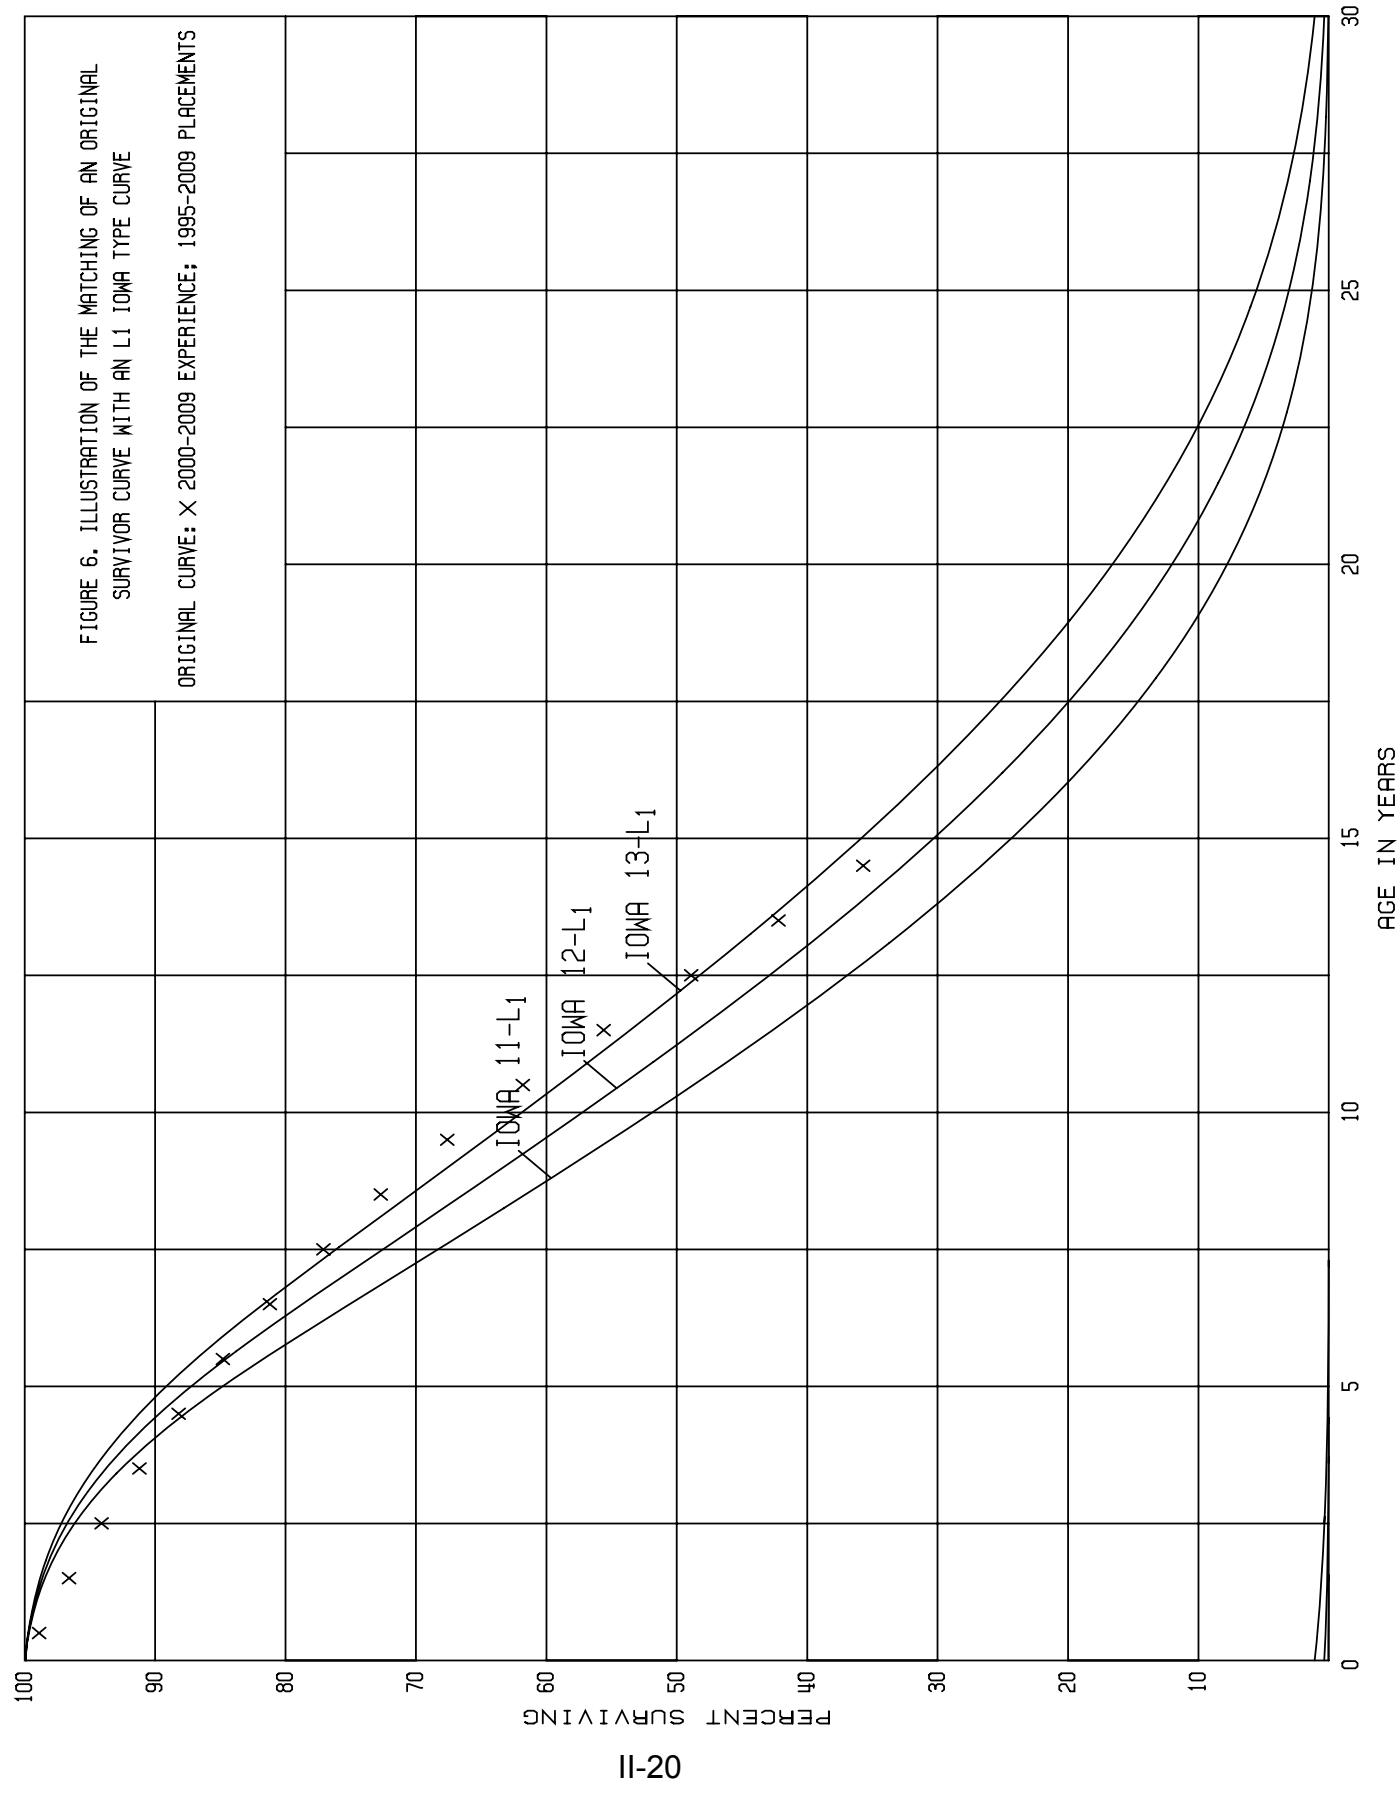

Column 6 = Column 5 multiplied by Column 6 as of the Preceding Age Interval.

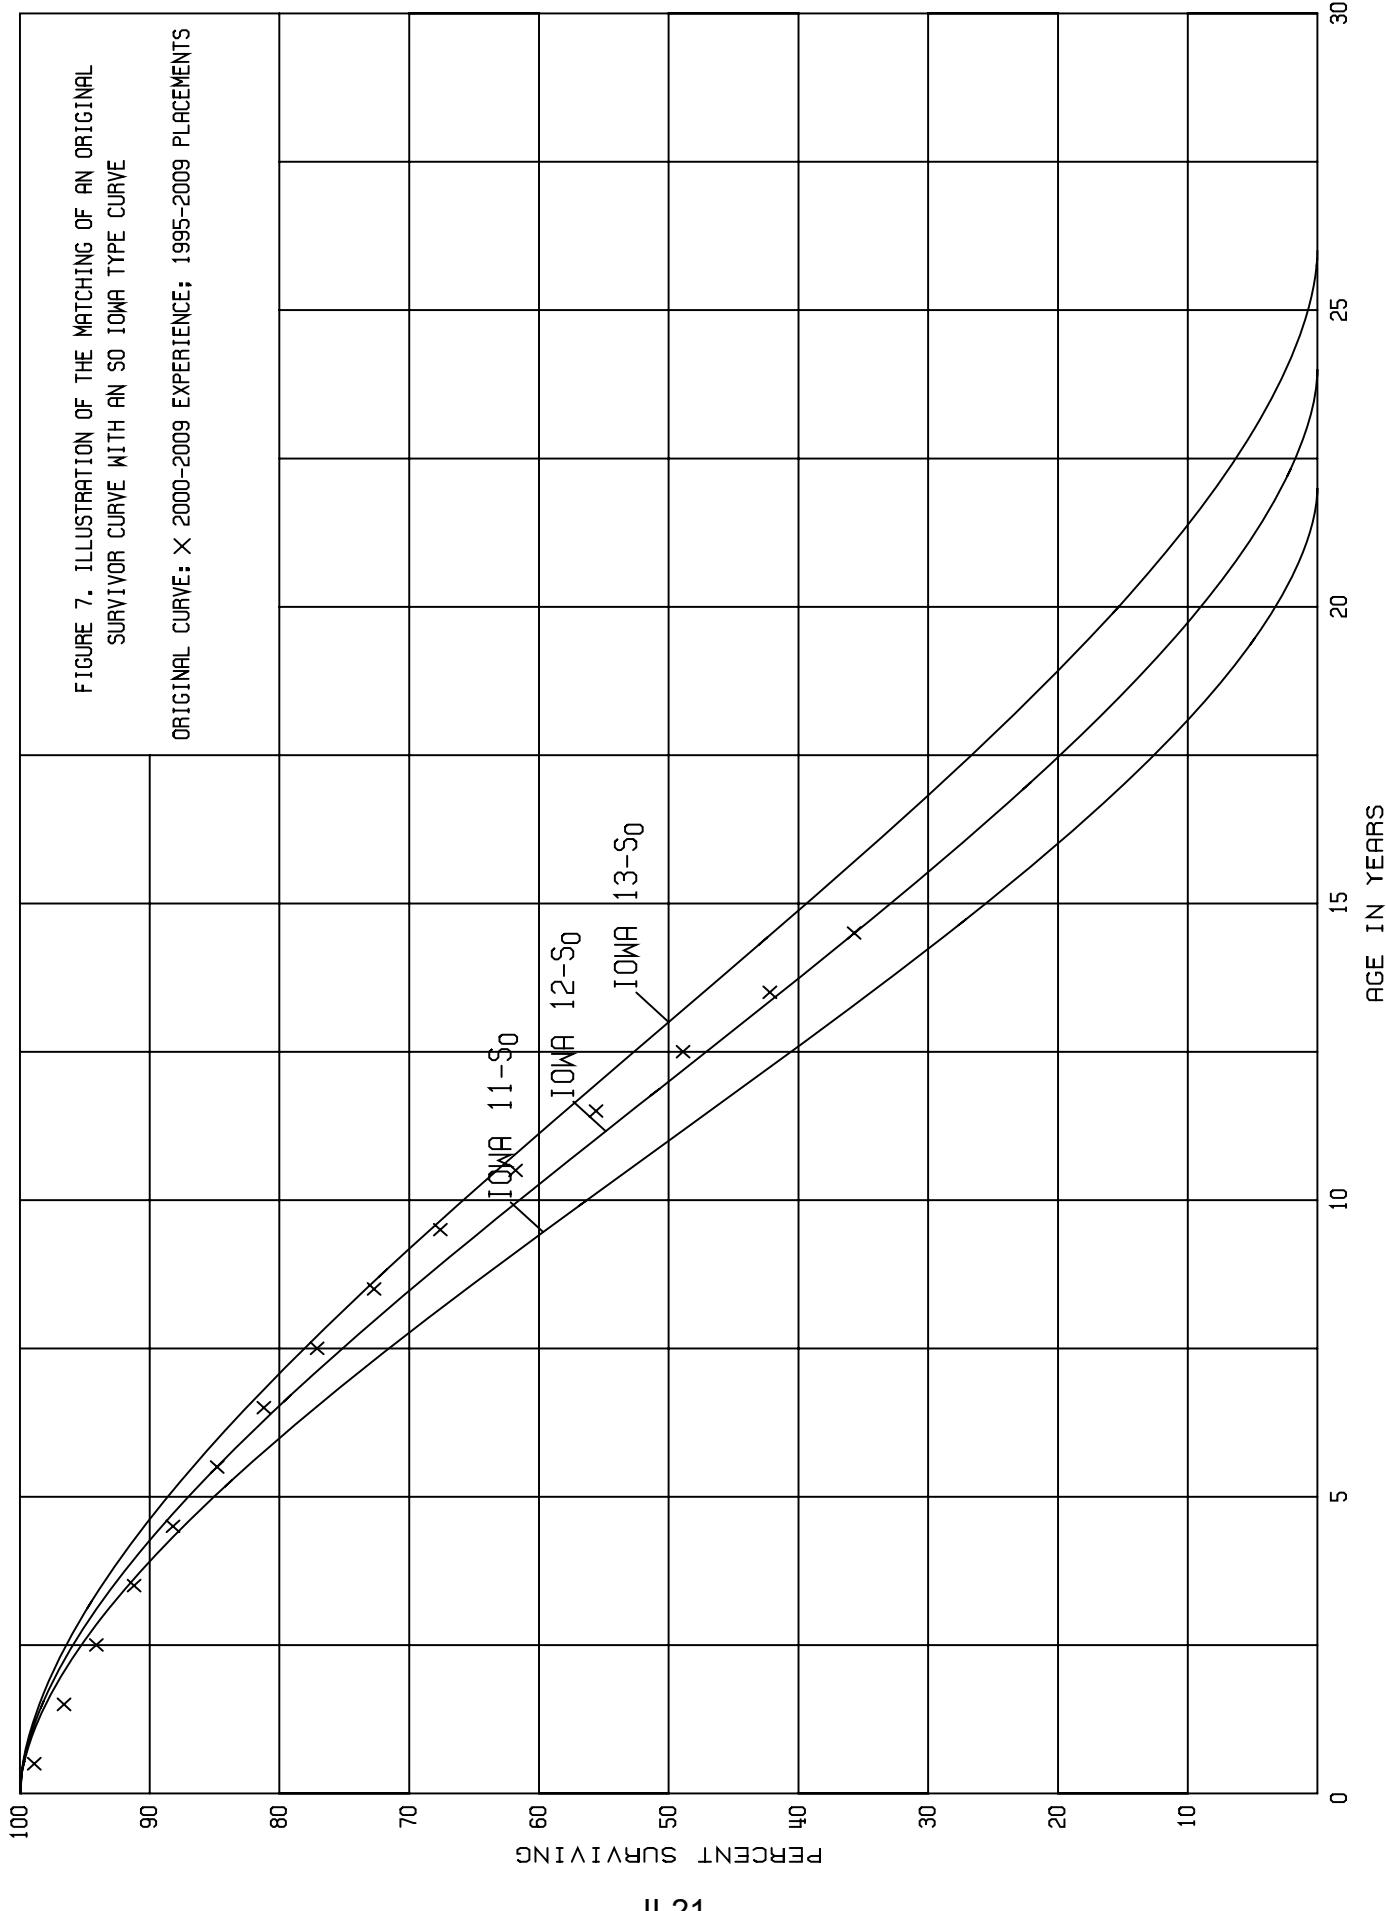

The Iowa type curves are used in this study to smooth those original stub curves which are expressed as percents surviving at ages in years. Each original survivor curve was compared to the Iowa curves using visual and mathematical matching in order to determine the better fitting smooth curves. In Figures 6, 7, and 8, the original curve developed in Table 4 is compared with the L, S, and R Iowa type curves which most nearly fit the original survivor curve. In Figure 6, the L1 curve with an average life between 12 and 13 years appears to be the best fit. In Figure 7, the S0 type curve with a 12-year average life appears to be the best fit and appears to be better than the L1 fitting. In Figure 8, the R1 type curve with a 12-year average life appears to be the best fit and appears to be better than either the L1 or the S0.

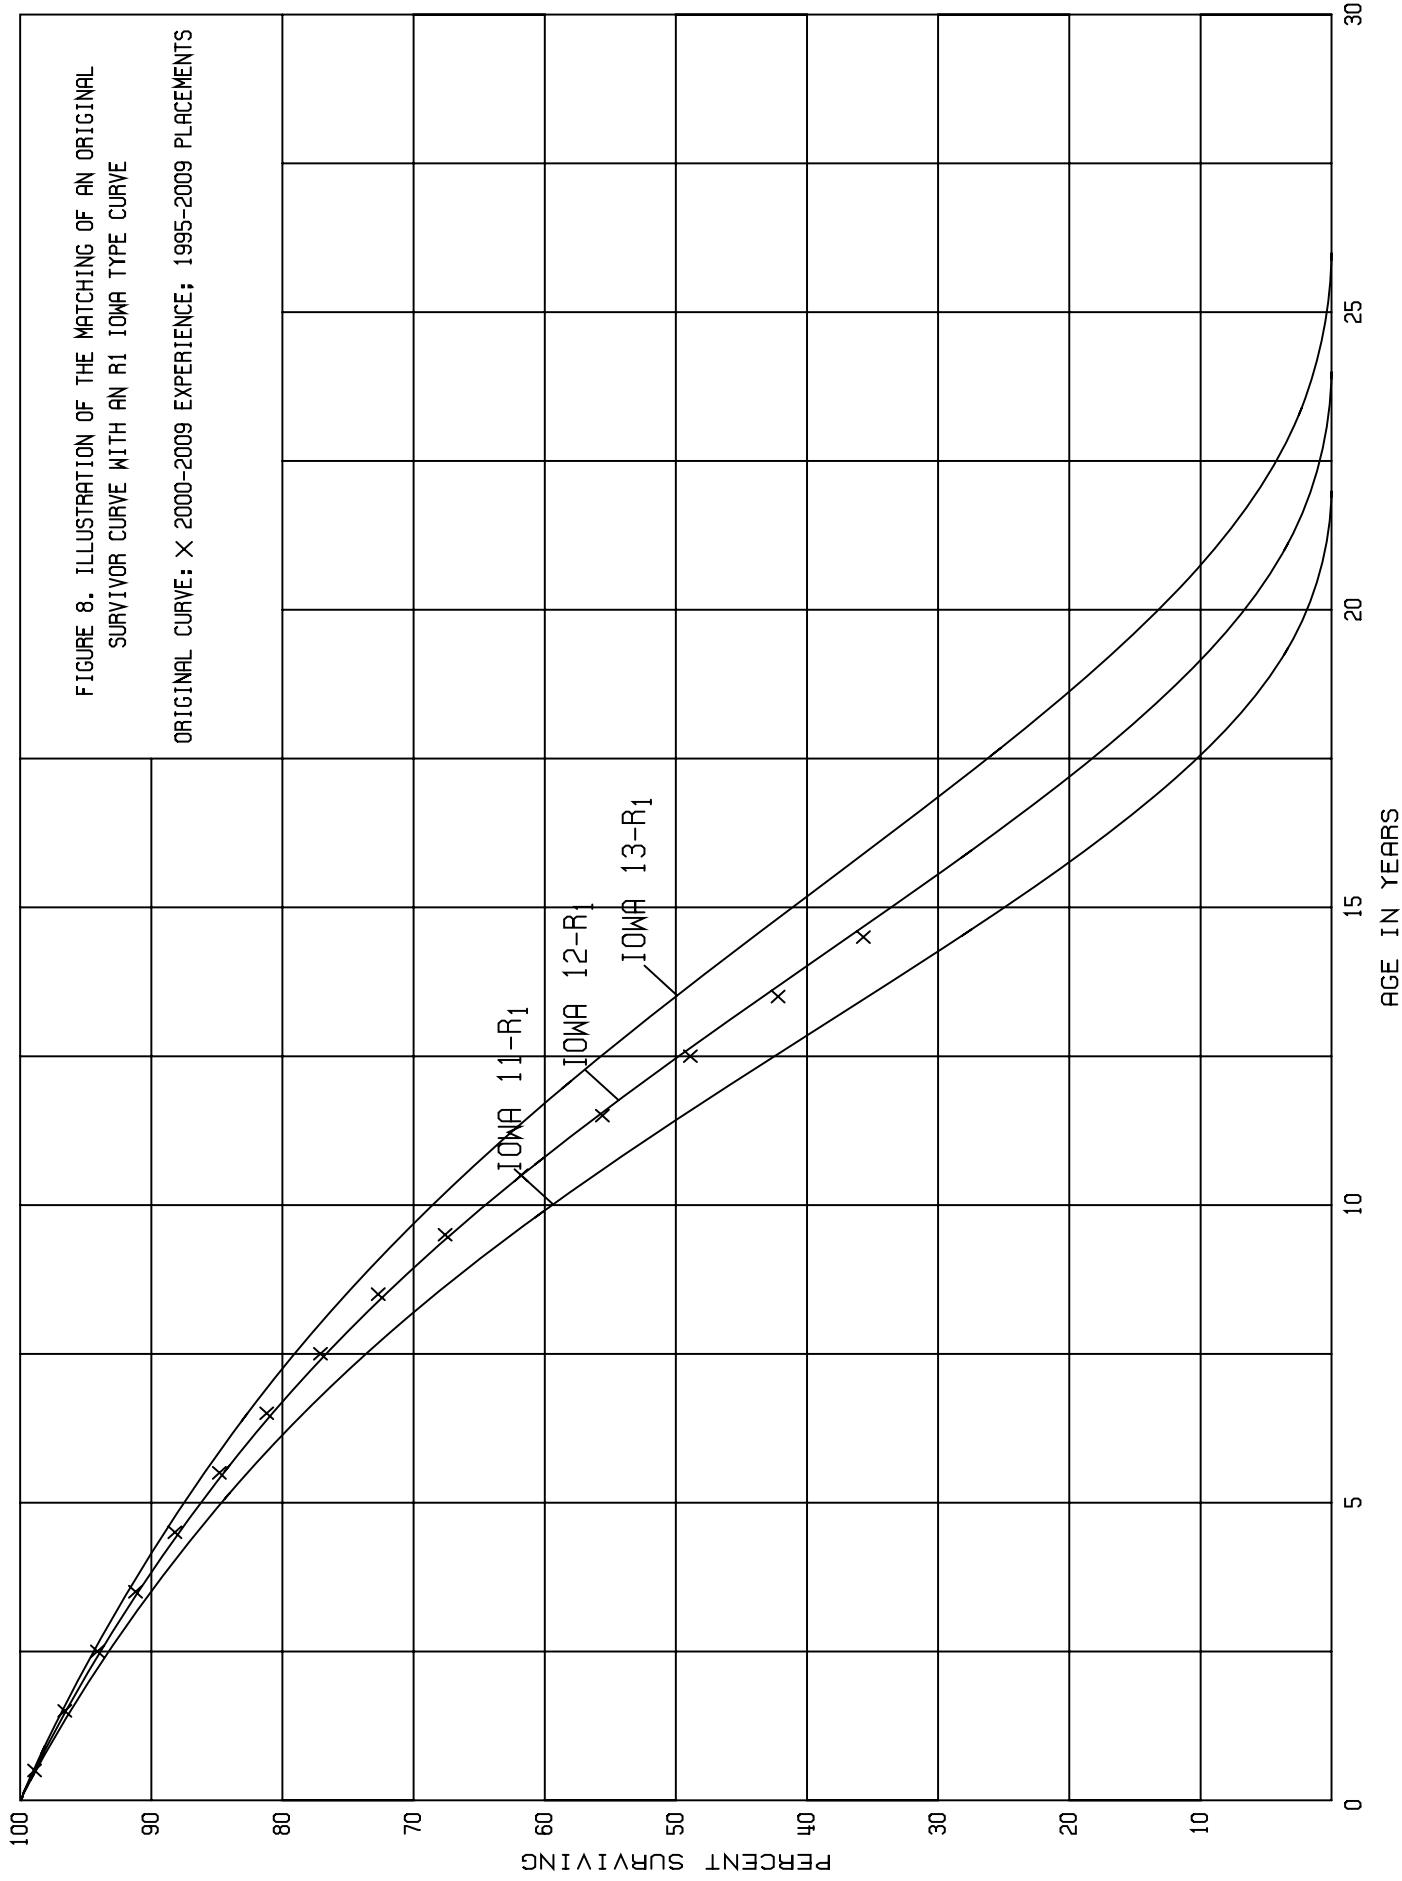

In Figure 9, the three fittings, 12-L1, 12-S0 and 12-R1 are drawn for comparison purposes. It is probable that the 12-R1 Iowa curve would be selected as the most representative of the plotted survivor characteristics of the group.

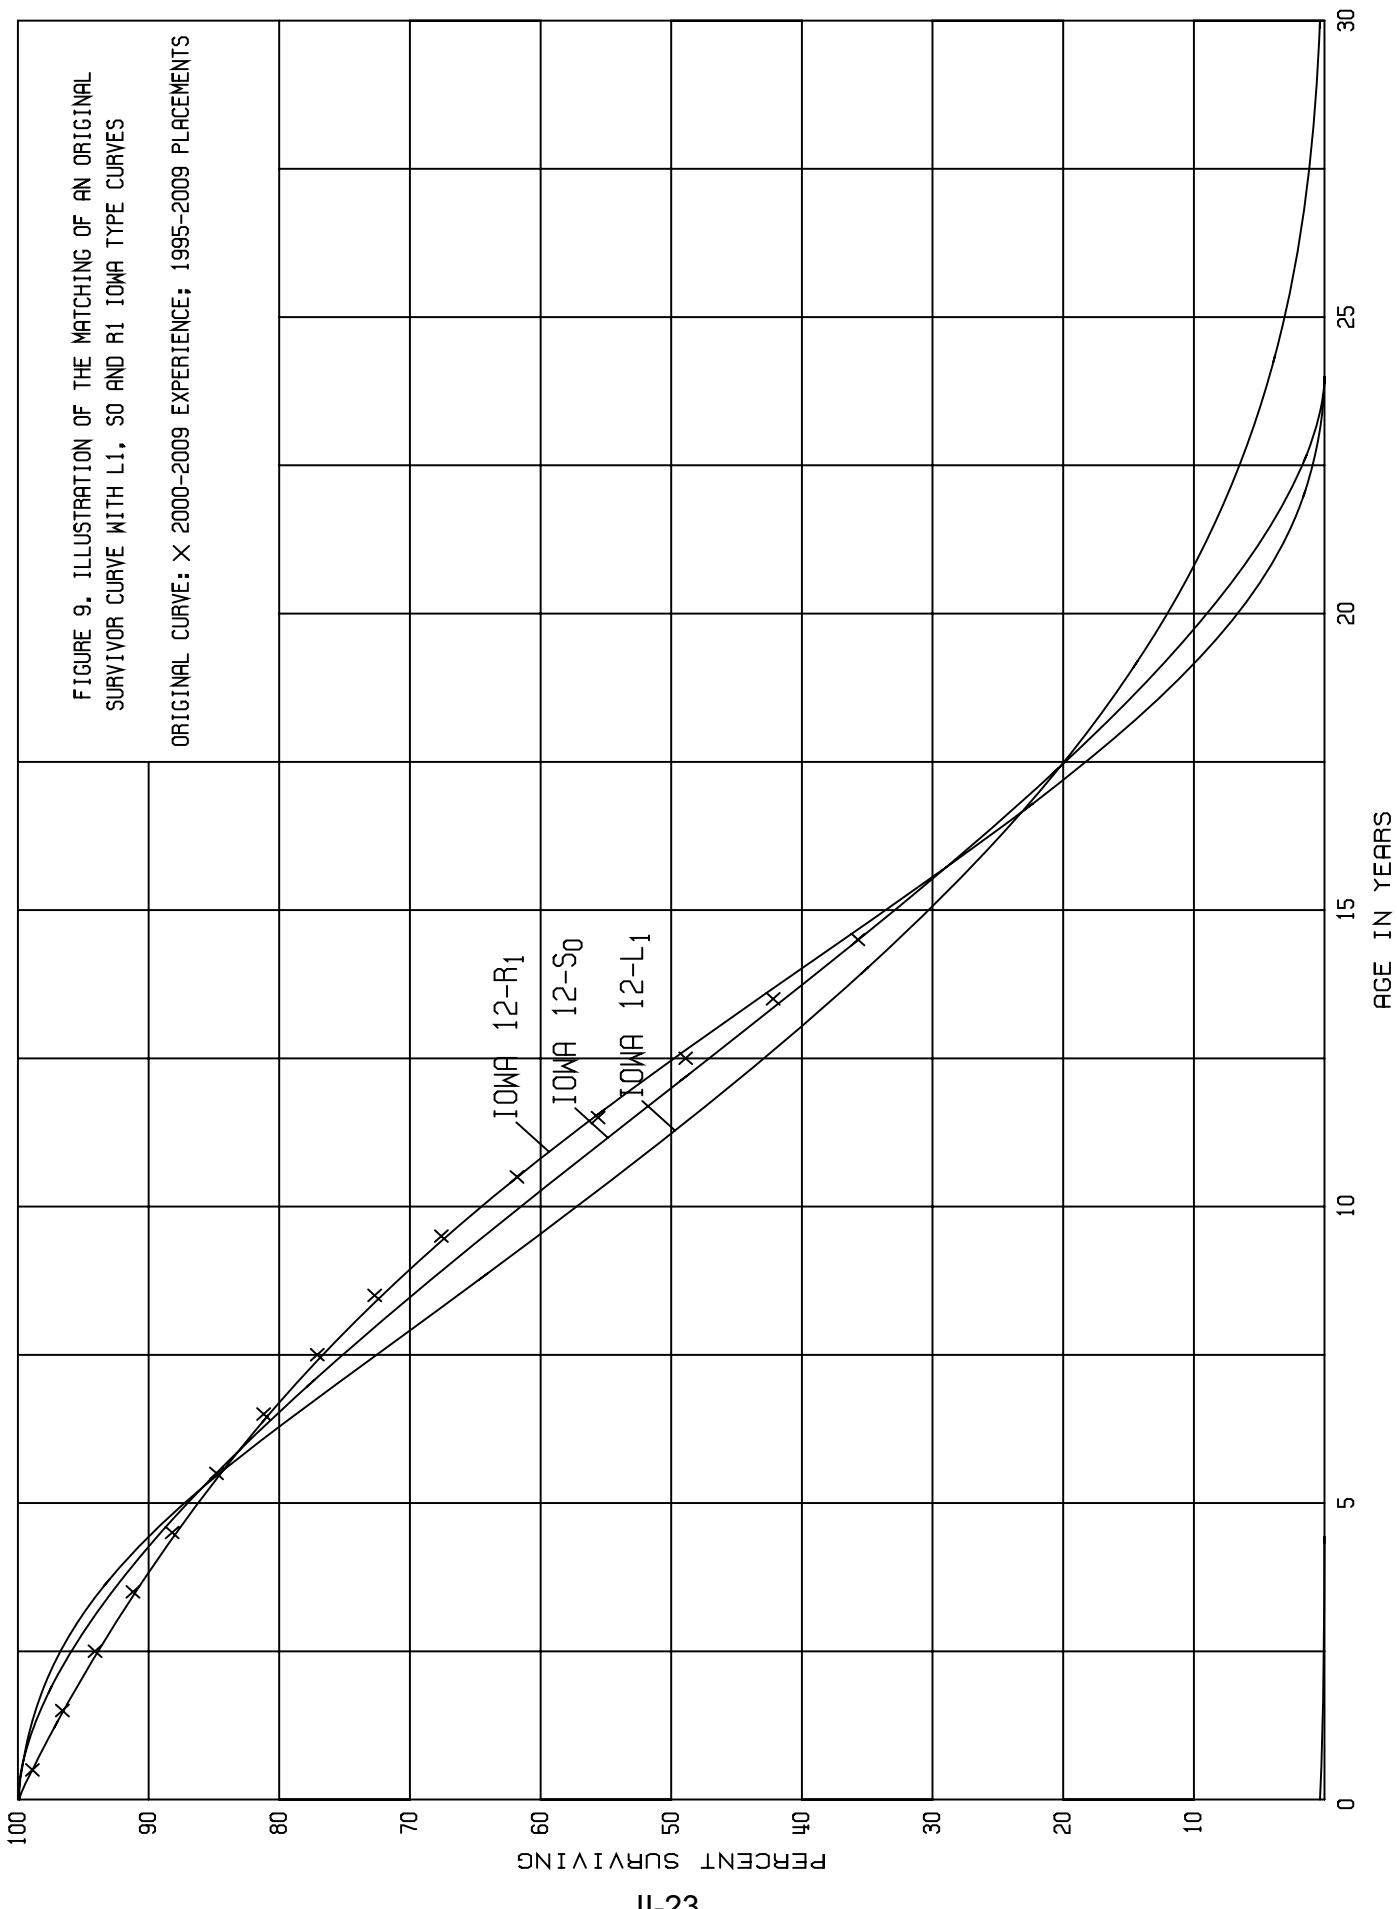

Survivor Curve Judgments. The survivor curve estimates were based on judgment which considered a number of factors. The primary factors were the statistical analysis of data; current policies and outlook as determined during conversations with management personnel; and average service life estimates from previous studies of this Company and other natural gas distribution companies.

Following is a discussion for the major accounts of Gaz Metro, and the manner in which the average service life estimate was made. The following discussion focuses on the accounts for which the average service life estimate was made based on the

retirement rate analysis as discussed in prior section of this report. While the following discussion focuses on the large accounts, all accounts studied using the retirement rate analysis were analyzed in the same manner.

Account Z1100, Distribution Services - Steel – represents approximately 5% of the depreciable distribution plant studied. The retirements, additions and other plant transactions for the period 1957 through 2009 were analyzed using the retirement rate analysis method. The original survivor curve, as plotted on page IV-2, indicates a trend of significant retirement ratios beginning early in the life of the account and continuing at a constant rate through the 52 year observation period. The high frequency of early retirement ratios is typical of distribution plant of this type and leads to a low mode Iowa curve. The previously used Iowa curve estimate of the Iowa 33-R2 for this account, appears to be too short and of too high of a mode. The statistical analysis provides for an Iowa curve of the 50-R1.5.

The discussions held with the company operations and engineering staff indicated that the continued use of a 33 year life is too short, which is consistent with the retirement rate analysis results. A move from the current 33 year life to a 50 year life (an increase of over 50%) is deemed by Gannett Fleming and the company management to be too large to make within the scope the scope of one depreciation study. Gannett Fleming also notes that the Iowa 45-R1.5 provides a good fit to the historic retirement ratios through age 30, which represents a 30 year period of the most significant investment exposed to retirement.

The 45-R1.5 Iowa curve provides a good interpretation of the historical data for the first 30 years of the accounts life meets the expectations of the company operating

staff and provides a life extension of 12 years. This account will be closely monitored in future depreciation studies to determine if further life extension continues to be apparent.

Account Z1102 – Distribution Services - Plastic, represents approximately 19% of the depreciable distribution plant studied. The retirements, additions and other plant transactions for the period 1977 through 2009 were analyzed with the retirement rate method. The original survivor curve, as plotted on page IV-8, indicates consistent retirement ratios through to age 32. The early retirement in this account occurs at a lesser rate than occurs in the other larger distribution plant accounts, and is consistent with industry trends for plant of this type. The previously used Iowa curve estimate for this account was the Iowa 35-R2. The retirement rate analysis indicated an increase in the Iowa curve estimate to the Iowa 50-R2.5. Typical average service lives for plastic gas distribution services range from 33 to 55 years, with most being at least 50 years.

Gannett Fleming interviews of Operations and Engineering staff related to this account, indicated that the expectations of the company is that the plastic distribution services should last at least 50 years on average and would have a maximum life of much more than 50 years. The 50-R2.5 Iowa curve, provides a good interpretation of the historical data, and is forecast to be representative of the anticipated future retirement activity.

Account Z1150 – Distribution Mains – Steel represents approximately 23% of the depreciable plant studied. The retirements, additions and other plant transactions for the period 1957 through 2009 were analyzed with the retirement rate method. The original survivor curve, as plotted on page IV-15, low retirement ratios through age 35 and then

significantly increasing ratios of retirement thereafter through to the end of the observation period this type of a trend in retirement ratios is consistent with a higher mode R Iowa curve. The previously used Iowa curve estimate for this account was the Iowa 42-R4. The retirement rate analysis indicated an increase in average service life estimate to 65 years and a reduction in the mode from an R4 curve to the R3 curve.

Gannett Fleming has maintained the indication of the Iowa R3 curve in the recommendations of this report, however a move from the current 42 year life to a 65 year life (an increase of over 50%) is deemed by Gannett Fleming and the company management to be too large to make within the scope the scope of one depreciation study. Typical average service lives for plastic gas distribution mains range from 50 to 70 years, with most being at least 50 years.

Gannett Fleming interviews of Operations and Engineering staff related to this account, indicated that the expectations of the company is that the plastic distribution mains should last at least 50 years on average and would have a maximum life of much more than 50 years. The 50-R3 Iowa is forecast to be representative of the anticipated future retirements of this account. However, this account will be monitored in future studies to determine if a further life extension is required.

Account Z1151 - Distribution Mains - Plastic, represents approximately 25% of the depreciable plant studied. Historical retirements, additions and other plant transactions for the period 1972 through 2009 were analyzed with the retirement rate method. The original survivor curve, as plotted on page IV-18, indicates very limited retirement activity through the observation period of this account to date. Typical Iowa

curve estimates for this type of plastic distribution mains usually range from 50 to 75 years. The previously approved Iowa curve estimate for this account was the 50-R3.

Given the limited amount of retirement activity experienced to date, the results of the retirement rate analysis were used only for the determination that this account should maintain the use of a higher mode R Iowa curve and that the current 50 year average service life estimate is likely to short. These assumptions were confirmed with the interviews held with the Operations and Engineering staff.

The Iowa 60-R3 recommended in this study provides recognition to the limited historic retirement experience, is within the range typically used by industry, and provides for a reasonable expectation of the future retirement trends.

Account Z1200 Distribution Meters represent approximately 5% of the depreciable plant studied. Plant accounting transactions from 1956 through 2009 were analyzed with the retirement rate method. The original survivor curve, as plotted on page IV-22, indicates a significant amount of retirement activity in this account through the complete observation period. The retirement rate analysis provided an Iowa curve estimate of the Iowa 24-R.5. The currently approved Iowa curve estimate is the Iowa L2-22.

Gannett Fleming held interviews with the company's internal experts in the area of metering, and toured the company's metering shop. Recent pronouncements made by Measurement Canada lead the company to believe that the older analog natural gas metering equipment will undergo a period of significant retirement activity, as it will be difficult for the existing analog meters to pass the new stringent testing requirements. Gannett Fleming has witnessed a trend in recent depreciation studies of natural gas

plant where the increased use of digital metering equipment has caused the typical average service life estimates for this equipment to be reduced from the previous 25 to 35 year range to 15 or 20 years. The company's internal metering experts indicated that some of the casing material may have a life expectation of approximately 20 years and the internal component parts would have an estimated life of 15 years. Gannett Fleming notes that this experience and expectation is now being common in the natural gas distribution industry.

Gannett Fleming recommends a decrease to the recommended 18 – R1.5 based on the comments of the company's internal experts, and the experience of Gannett Fleming within the natural gas industry.

Account Z3100 – Transmission Mains represent approximately 10% of the depreciable plant studied. Plant accounting transactions from 1983 through 2009 were analyzed with the retirement rate method. The original survivor curve, as plotted on page IV-44, indicates that no retirement activity has occurred over this observation period. As such the average service life estimate of this account was based on the professional judgment of Gannett Fleming.

Gannett Fleming has completed a number of depreciation studies for Canadian natural gas and crude oil transmission systems. Based on this experience Gannett Fleming recommends the use of the Iowa 65-R3 at this time.

The survivor curve estimates for the remaining accounts, were based on similar considerations of historical analyses, management outlook and estimates for the company and other natural gas distribution utilities.

Net Salvage Estimates. The estimates of net salvage were based primarily on the professional judgment of Gannett Fleming, in part on historical data for the years 2002 through 2009, and in part through a comparison to peer gas transmission and distribution companies. Gross salvage and cost of removal as recorded to the depreciation reserve account and related to experienced retirements were used. Percentages of the cost of plant retired were calculated for each component of net salvage on both annual and five-year moving average bases.

When a natural gas utility retires a plant, the plant may be: (1) sold to a third party; (2) re-used by the utility for additional service; (3) abandoned in place; or (4) physically removed. In the circumstances where the plant is sold or re-used a salvage proceed (or positive salvage amount) is normally recognized. In circumstances where the plant is abandoned in place or physically removed, a cost of removal expenditure (or negative salvage) is incurred. The net of these estimated gross salvage proceeds and the estimated costs of removal are expressed as a percentage of the accounts original cost to determine a net salvage percentage. In the circumstances where the salvage proceeds exceed the costs of retirement a net positive salvage percentage exists. In the circumstances where the costs of removal exceed the salvage proceeds, a net negative salvage percentage results.

The estimation of the Net Salvage percentages developed in this study included the following steps:

1. The annual retirement, gross salvage and cost of removal transactions for the period from 2002 through 2009 were extracted from the plant accounting systems.
2. A net salvage amount (gross salvage proceeds less cost of retirement) was calculated for each historic year. Additionally, a net salvage

amount was also calculated for each historic 3-year moving average band, and the most recent 5-year rolling band.

3. The net salvage amount determined above was compared to the original booked costs retired for each period in the manner described, which resulted in a net salvage percentage of original costs retired for each year, in addition to the 3-year rolling and most recent 5-year bands.
4. The annual, 3-year rolling average, and most recent 5-year net salvage percentages were analyzed to determine a reasonable estimated net salvage percentage. At this point the net salvage percentage was based purely upon statistical analysis.
5. Each account was then analyzed based on the statistical analyses, were compared to a group of peer Natural Gas Utilities, and with the professional judgment of Gannett Fleming. Based on this analysis, a net salvage percentage for each account was determined. The professional judgment of Gannett Fleming included consideration of the discussions held with the Gaz Metro operational and management staff.

The statistical analysis of the net salvage transactions analyzed for each account is provided in the Net Salvage Statistics section of this report.

CALCULATION OF ANNUAL AND ACCRUED DEPRECIATION

Group Depreciation Procedures. When more than a single item of property is under consideration, a group procedure for depreciation is appropriate because normally all of the items within a group do not have identical service lives, but have lives that are dispersed over a range of time. There are two primary group procedures, namely, average service life and equal life group.

In the average service life procedure, the rate of annual depreciation is based on the average life or average service life of the group, and this rate is applied to the surviving balances of the group's cost. A characteristic of this procedure is that the cost

of plant retired prior to average life is not fully recouped at the time of retirement, whereas the cost of plant retired subsequent to average life is more than fully recouped. Over the entire life cycle, the portion of cost not recouped prior to average life is balanced by the cost recouped subsequent to average life. In this procedure, the accrued depreciation is based on the average service life of the group and the average remaining life of each vintage within the group derived from the area under the survivor curve between the attained age of the vintage and the maximum age.

In the equal life group procedure, the property group is subdivided according to service life. That is, each equal life group includes that portion of the property which experiences the life of that specific group. The relative size of each equal life group is determined from the property's life dispersion curve. The calculated depreciation for the property group is the summation of the calculated depreciation based on the service life of each equal life group. The table on the following page presents an illustration of the calculation of equal life group depreciation using the Iowa 18-R15 survivor curve, 0 percent net salvage and a December 31, 2009 calculation date. In the table, each equal life group is defined by the age interval shown in columns 1 and 2. These are the ages at which the first and last retirement of each group occurs, and the group's equal life, shown in column 3, is the midpoint of the interval. For purposes of the calculation, each vintage is divided into equal life groups arranged so that the midpoint of each one-year age interval coincides with the calculation date, e.g., December 31 in this case. This enables the calculation of annual accruals for a twelve-month period centered on the date of calculation.

The retirement during the age interval, shown in column 4, is the size of each equal life group and is derived from the Iowa 18-R15 survivor curve and 0 percent net salvage. It is the difference between the percents surviving at the beginning and end of the age interval. Each equal life group's annual accrual, shown in column 5, equals the group's size (column 4) divided by its life (column 3).

Columns 6 through 10 show the derivation of the annual and accrued factors for each vintage based on the information developed in the first five columns. The year installed is shown in column 6. For all vintages other than 2009, the summation of annual accruals for each year installed, shown in column 7, is calculated by adding one-half of the group annual accrual (column 5) for that vintage's current age interval plus the group annual accruals for all succeeding age intervals. For example, the figure 7.53413204309 for 2008 equals one-half of 0.14669333333 plus all of the succeeding figures in column 5. Only one-half of the annual accrual for the vintage's current age interval group is included in the summation because the equal life group for that interval has reached the year during which it is expected to be retired.

The summation of annual accruals (column 7) for installations during 2009 is calculated on the basis of an in-service date at the midpoint of the year, i.e., June 30. Inasmuch as the overall calculation is centered on December 31, 2009, the first figure in column 7, for vintage 2009, equals all of the group annual accrual for the first equal life group plus the accruals for all of the subsequent equal life groups.

TOTAL			100.00000						

The average percent surviving derived from the Iowa 15-R3 survivor curve and 0 percent net salvage is shown in column 8 for each age interval. The annual factor, shown in column 9, is the result of dividing the summation of annual accruals (column 7) by the average percent surviving (column 8). The accrued factor, shown in column 10, equals the annual factor multiplied by the age of the group at December 31, 2009.

The use of the ELG procedure in this study represents a change in the grouping procedure from the use of the ASL procedure used in previous Gaz Metro studies. In the view of Gannett Fleming the ELG procedure provides a superior conformance to the IFRS standards which require the depreciation of an asset over its specific life. The ELG procedure is premised on the recovery of capital investment over the estimated life of each specific equal life group within each vintage. The use of the ASL procedure relies on the long life assets to recover the shortfall of depreciation from the short life assets which never had the opportunity to be fully recovered. While it is Gannett Fleming's understanding that the ASL procedure is acceptable for the determination of the annual depreciation accrual for IFRS purposes, use of the ASL procedure will result in an increased amount of losses being charged to the income statement of the utility.

Gannett Fleming also notes that the use of the ELG method eliminates the inter-generational inequities that are caused by the ASL method. Because the depreciation expense is aligned with the consumption of service value, ratepayers at any point in time are only charged with the depreciation expense associated with the consumption of service value of assets for which those same ratepayers had the benefit of service.

PART III. RESULTS OF STUDY

PART III. RESULTS OF STUDY

QUALIFICATION OF RESULTS

The calculated annual and accrued depreciation and the calculation of the composite average remaining life are the principal results of the study. Continued surveillance and periodic revisions are normally required to maintain continued use of appropriate annual depreciation accrual rates. An assumption that accrual rates can remain unchanged over a long period of time implies a disregard for the inherent variability in service lives and salvage and for the change of the composition of property in service. The annual accrual rates and the accrued depreciation were calculated in accordance with the straight line method, using the equal life group procedure based on estimates which reflect considerations of current historical evidence and expected future conditions.

DESCRIPTION OF DETAILED TABULATIONS

The service life estimates were based on judgment that incorporated statistical analysis of retirement data, discussions with management and consideration of estimates made for other natural gas distribution utilities. The results of the statistical analysis of service life are presented in the supporting materials document beginning on page IV-2.

For each depreciable group analyzed by the retirement rate method, a chart depicting the original and estimated survivor curves is followed by a tabular presentation of the original life table(s) plotted on the chart. The survivor curves estimated for the depreciable groups are shown as dark smooth curves on the charts. Each smooth survivor curve is denoted by a numeral followed by the curve type designation. The

numeral used is the average life derived from the entire curve from 100 percent to zero percent surviving.

The titles of the chart indicate the group, the symbol used to plot the points of the original life table, and the experience and placement bands of the life tables which were plotted. The experience band indicates the range of years for which retirements were used to develop the stub survivor curve. The placements indicate, for the related experience band, the range of years of installations that appear in the experience.

The tables of the calculated annual depreciation applicable to plant as of September 30, 2009 are presented in account sequence starting on page V-2. The tables indicate the estimated average survivor curves and net salvage percents used in the calculations. The tables set forth, for each installation year, the original cost, calculated accrued depreciation, and the calculated annual accrual.
